

UV signal of dust evolution in molecular cloud envelopes

Leire Beitia-Antero & Ana Inés Gómez de Castro
Universidad Complutense de Madrid

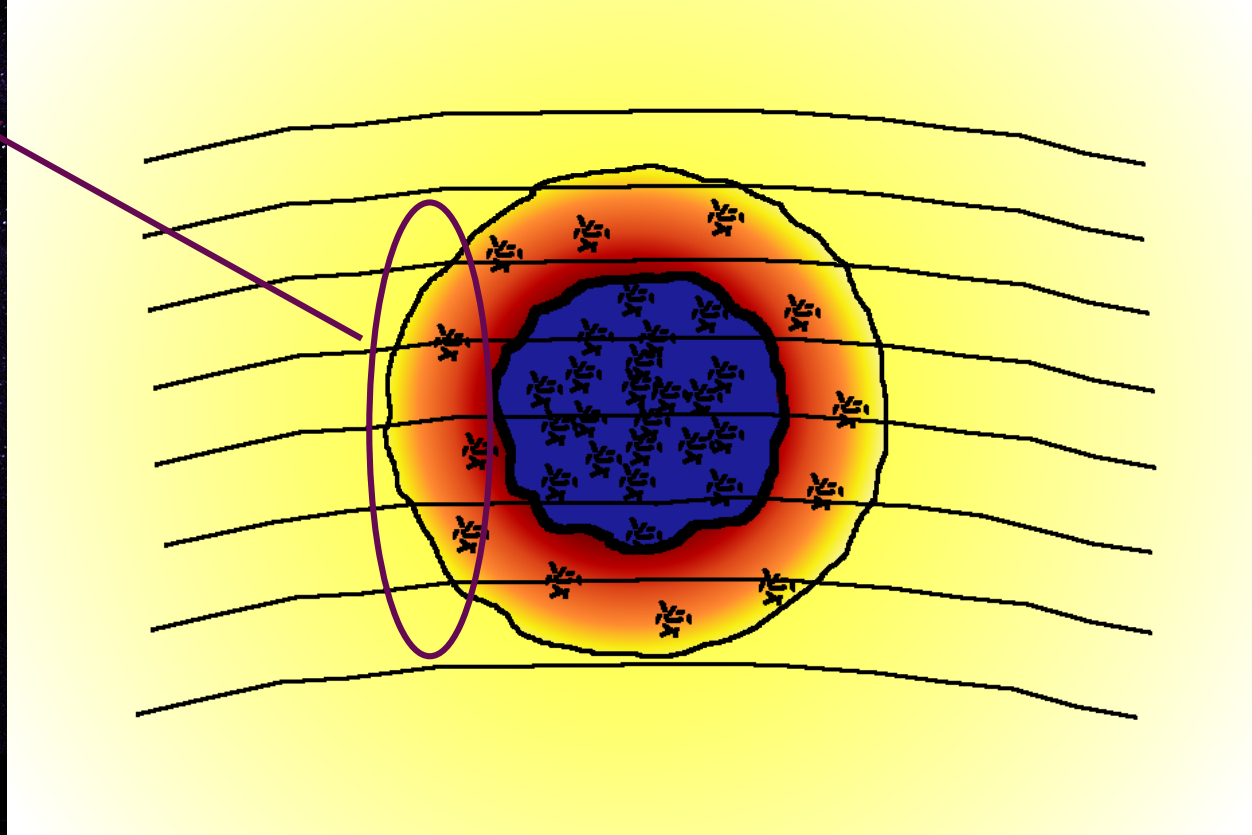

UV Astronomy in the XXIst century

MOLECULAR CLOUD ENVELOPE: WHAT IS IT?

Diffuse gas: 6000 K, $n \approx 0.1 - 10 \text{ cm}^{-3}$
Magnetic field coupling
Partially ionised (gas and dust)
WNM

Can be probed at UV wavelengths

WHY DUST IS IMPORTANT?

Dust grains affect the thermal/chemical evolution of the cloud

Absorption/scattering of UV photons
Photoelectric heating (net charge)
Molecule formation

WHY DUST IS IMPORTANT?

Dust grains affect the thermal/chemical evolution of the cloud

Absorption/scattering of UV photons
Photoelectric heating (net charge)
Molecule formation

Charged dust grains affect the dynamical evolution of the cloud

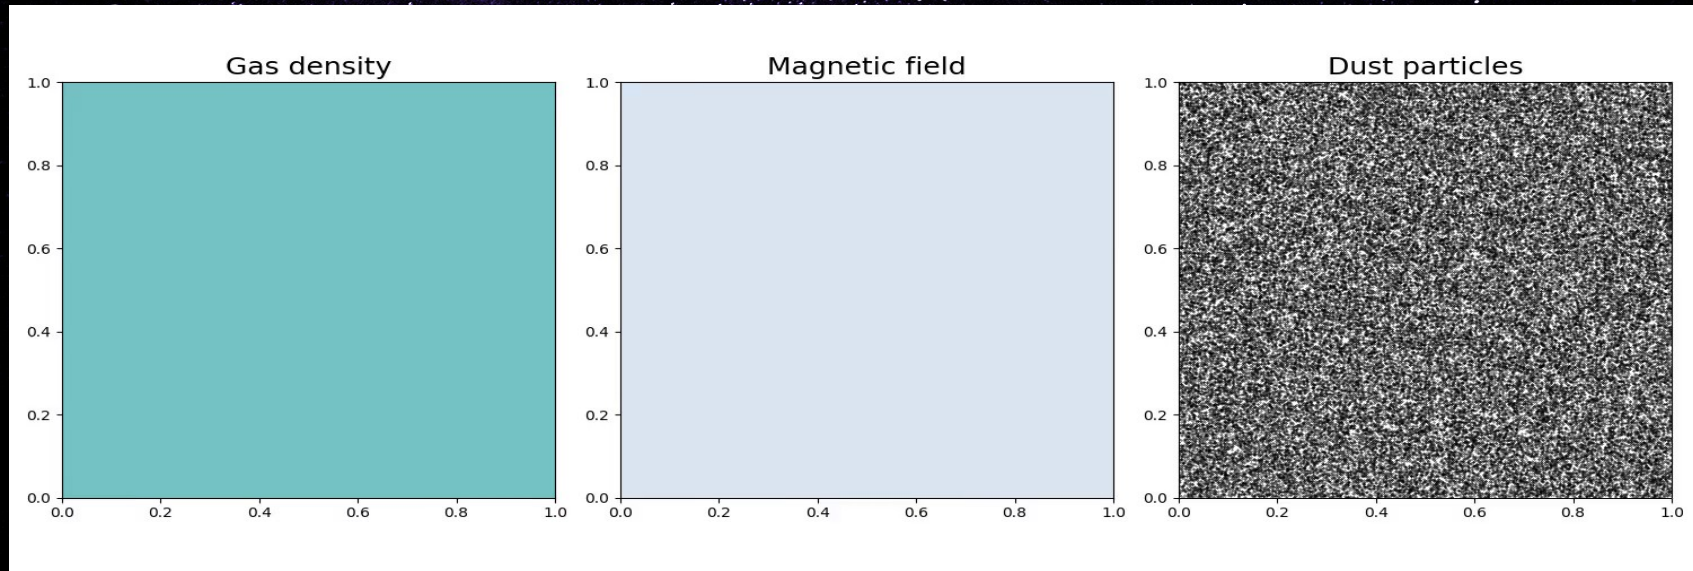

Simulating Diverse Instabilities of Dust in Magnetized Gas, Hopkins et al. (2020)

HOW DOES DUST MOVE INSIDE A MOLECULAR CLOUD ENVELOPE?

WNM-like conditions

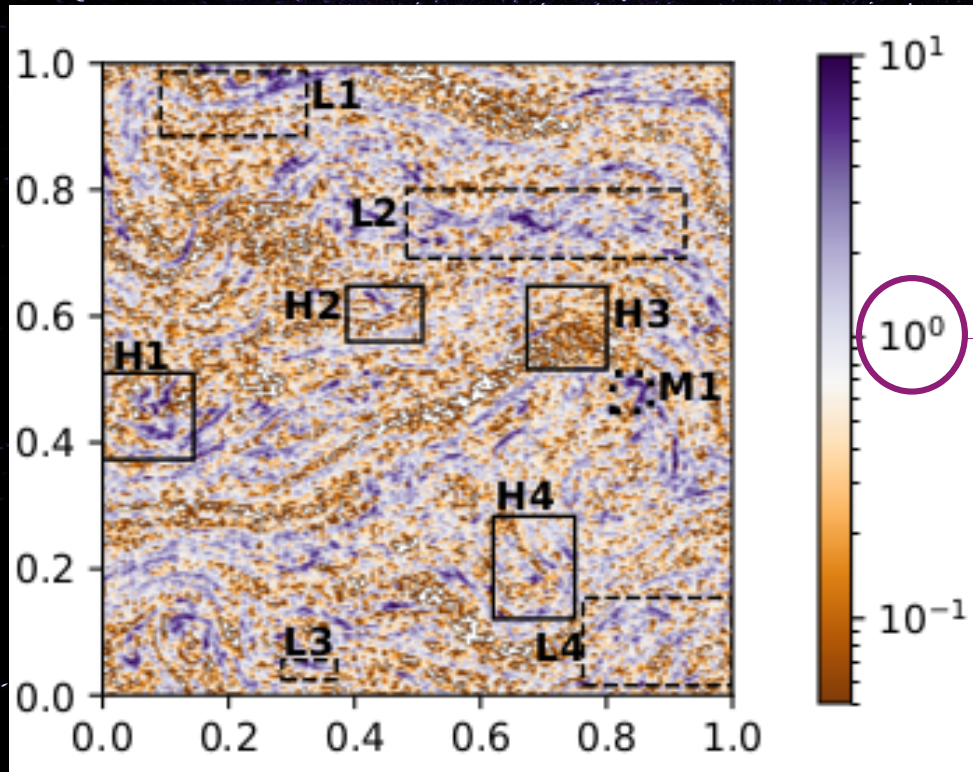

0.05 microns silicate grains ($Z = -17$)

Beitia-Antero et al. (2021)

DUST FILAMENTS IN MOLECULAR CLOUD ENVELOPES

Dust-to-gas ratio map (normalised)

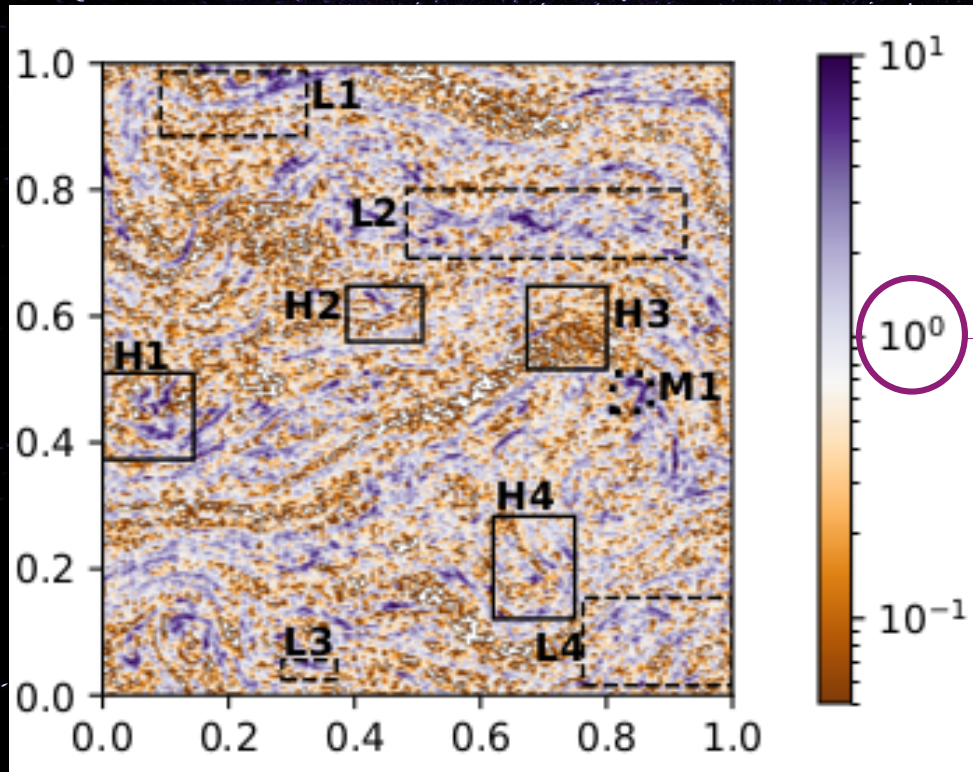

H1-4: regions of high density gas
L1-4: regions of low density gas

Nominal dust-to-gas ratio value
of 0.01

DUST FILAMENTS IN MOLECULAR CLOUD ENVELOPES

Dust-to-gas ratio map (normalised)

H1-4: regions of high density gas
L1-4: regions of low density gas

Nominal dust-to-gas ratio value
of 0.01

**WHAT HAPPENS INSIDE THOSE
FILAMENTS?**

A NEW ALGORITHM FOR DUST EVOLUTION IN MHD CODES

Let's assume that computational particles represent a swarm of real particles uniformly distributed around it

Mass of the computational particle: m
Represented total mass: M

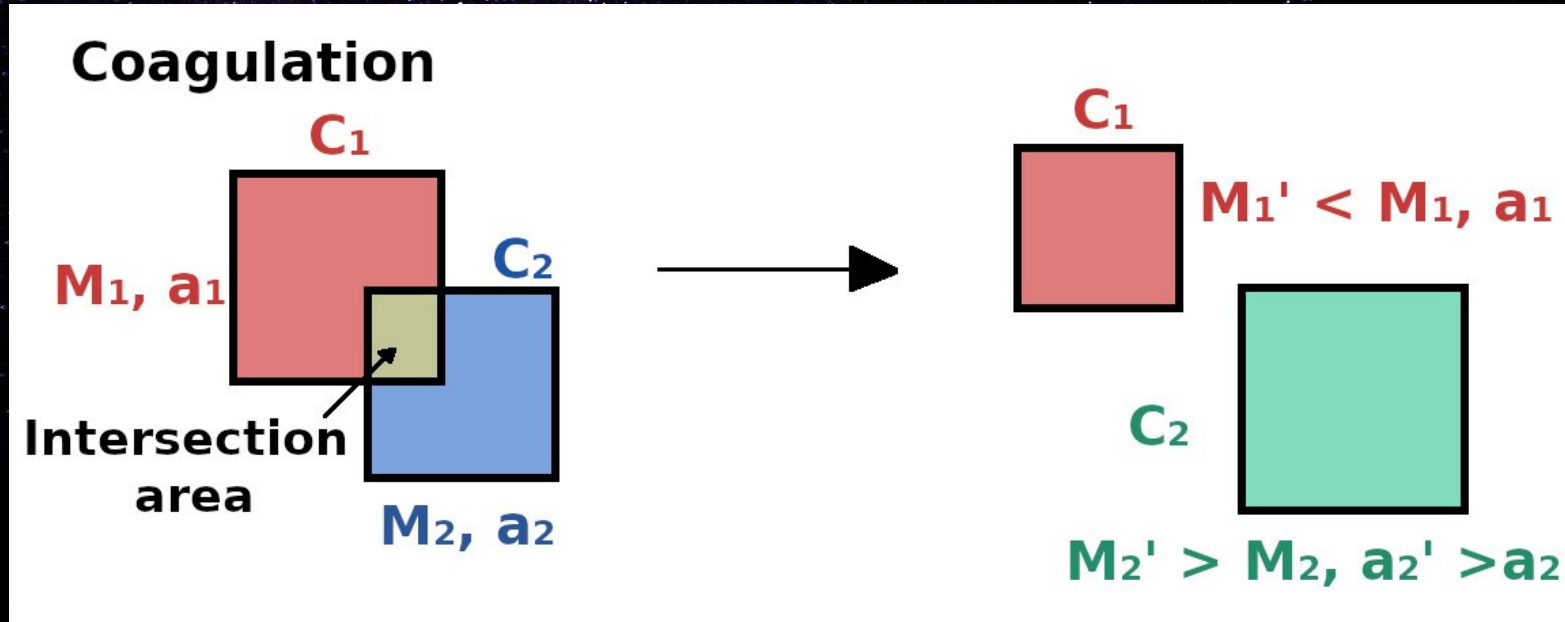

A NEW ALGORITHM FOR DUST EVOLUTION IN MHD CODES

In order to keep constant the total number of computational particles, particle-particle interactions are indirect (mass/momentum exchange)

A NEW ALGORITHM FOR DUST EVOLUTION IN MHD CODES

Simple dust evolution model – two possible outcomes: coagulation or shattering

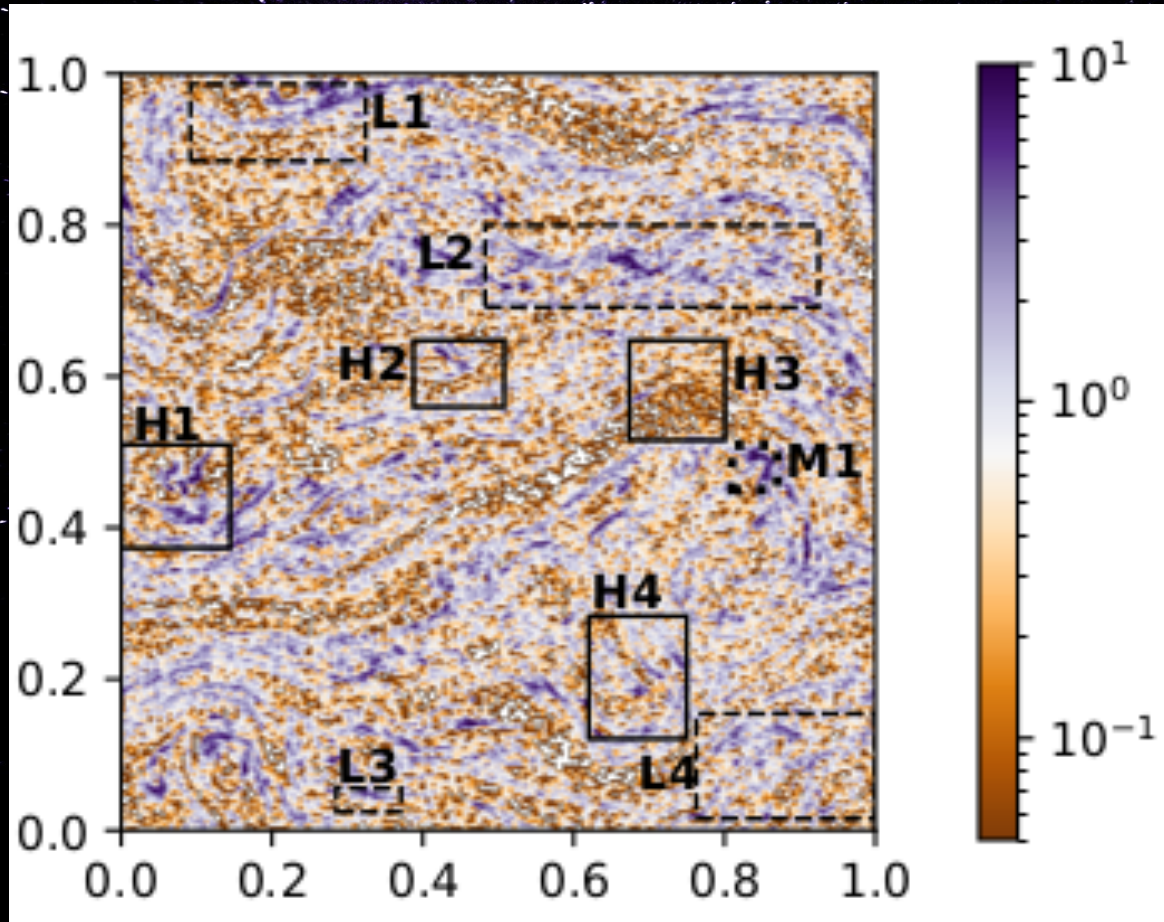

A NEW ALGORITHM FOR DUST EVOLUTION IN MHD CODES

Simple dust evolution model – two possible outcomes: coagulation or shattering

DUST EVOLUTION OF A SINGLE-SIZED DUST POPULATION

Dust evolution in regions H1, H2, H4, L1, L2, L4, M1 was followed

Particle positions and gas properties from final snapshot of MHD simulation

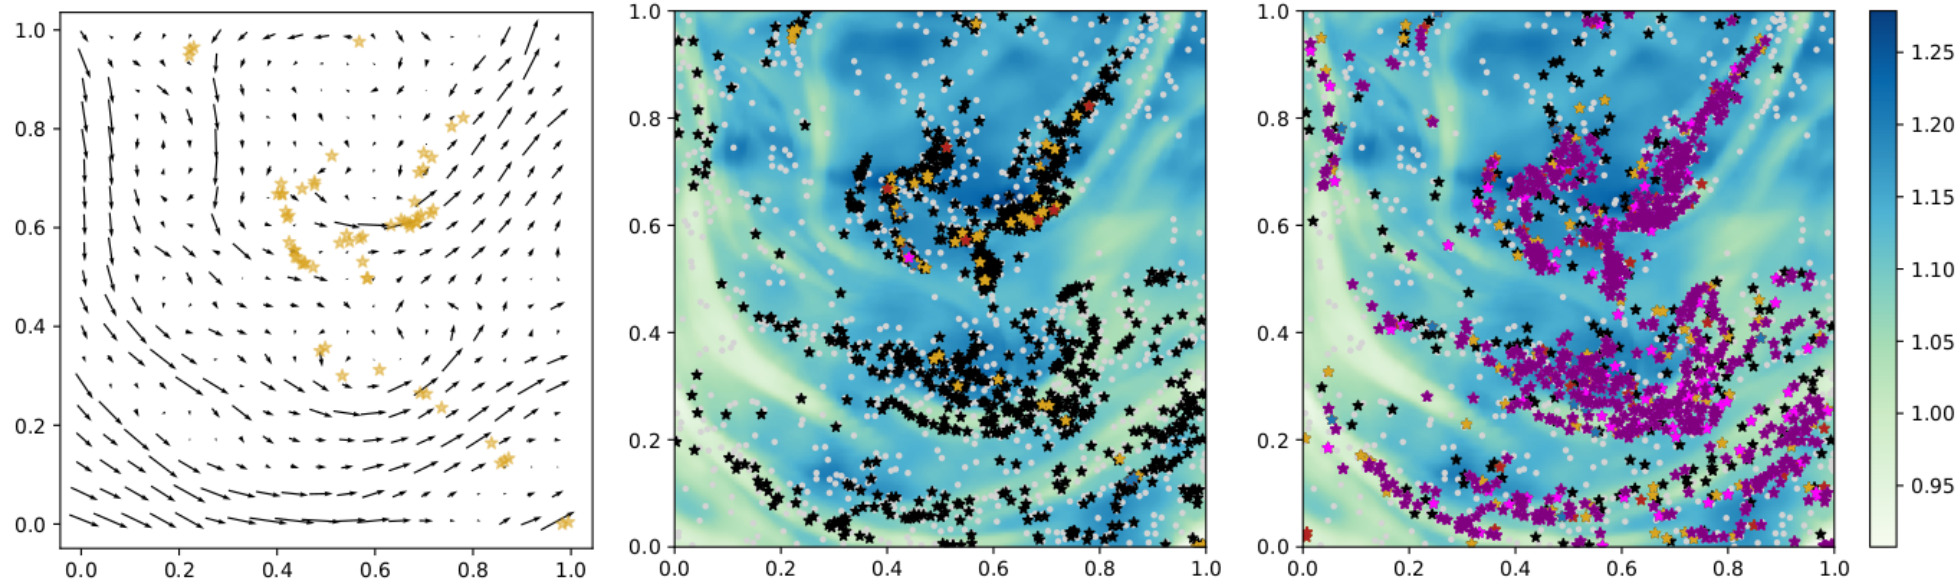

DUST EVOLUTION OF A SINGLE-SIZED DUST POPULATION

H1

DUST EVOLUTION OF A SINGLE-SIZED DUST POPULATION

H1

VARIATIONS IN THE DUST SIZE DISTRIBUTION

$$n(a) = K n_H a^q$$

We need a real dust size distribution, not a single sized population:
mock sample

Two populations: silicate and graphite
Dust masses equally distributed
Particle sizes between 50 Å and 0.25 μm (MRN), logarithmically sampled
100 test particles of each size
Random position according to dust size
(smaller ones follow the magnetic field, larger ones follow gas)

VARIATIONS IN THE DUST SIZE DISTRIBUTION

$$n(a) = K n_H a^q$$

Silicates and graphite evolve independently

Power law index q measured for each population and simulation

EFFECTS ON THE UV EXTINCTION CURVE

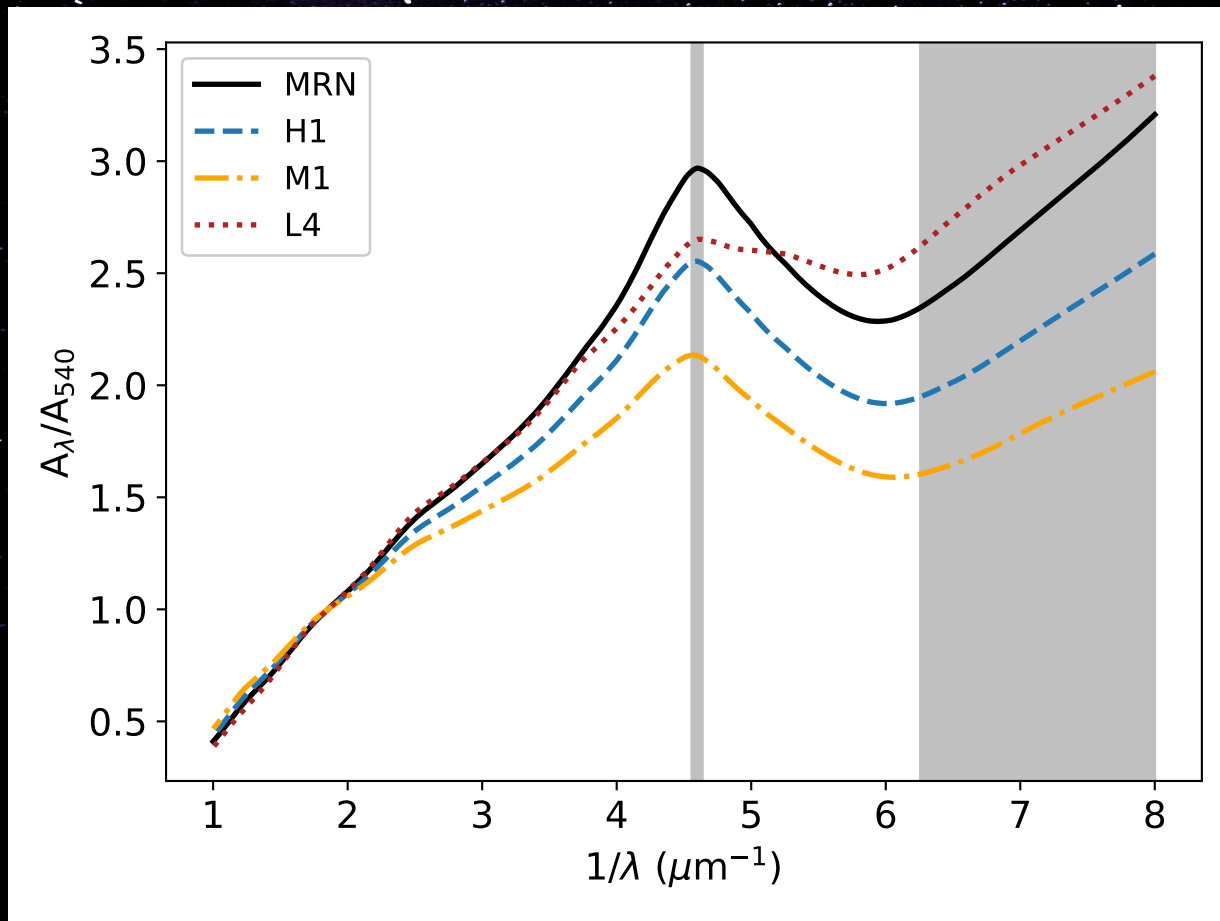

$$A_{\lambda} = 1.086 \left(\int_{a_{min}}^{a_{max}} \pi a^2 Q_{\lambda, sil}^{ext}(a) n_{sil}(a) da + \int_{a_{min}}^{a_{max}} \pi a^2 Q_{\lambda, gra}^{ext}(a) n_{gra}(a) da \right)$$

Nozawa & Fukugita 2013

$$\begin{aligned} a_{min} &= 50 \text{ \AA}, a_{max} = 0.25 \text{ \mu m} \\ n(a) &= K n_H a^q, K_{sil} = 10^{-25.11}, K_{gra} = 10^{-25.13} \\ Q_{\lambda} &: \text{extinction efficiency (Draine 2003)} \end{aligned}$$

q is computed by fitting the final size distributions
values range from -3.4 to -3.07.

EFFECTS ON THE UV EXTINCTION CURVE

Far-UV slope

$$b_{\text{FUV}}/b^{\text{MRN}}$$

$$\text{H1} = 0.76$$

$$\text{H2} = 0.79$$

$$\text{H4} = 0.75$$

$$\text{L1} = 0.78$$

$$\text{L2} = 0.75$$

$$\text{L4} = 0.86$$

$$\text{M1} = 0.55$$

WHICH DUST POPULATION EXERTS A GREATER INFLUENCE?

Far-UV slope

$$b_{\text{FUV}}/b^{\text{MRN}}$$

$$H1 = 0.76$$

$$H2 = 0.79$$

$$H4 = 0.75$$

$$L1 = 0.78$$

$$L2 = 0.75$$

$$L4 = 0.86 \longrightarrow \text{similar depletion of silicates and graphites}$$

$$M1 = 0.55 \longrightarrow \text{dust destruction very effective}$$

WHICH DUST POPULATION EXERTS A GREATER INFLUENCE?

Far-UV slope

$$b_{\text{FUV}}/b^{\text{MRN}}$$

$$\text{H1} = 0.76$$

$$\text{H2} = 0.79$$

$$\text{H4} = 0.75$$

$$\text{L1} = 0.78$$

$$\text{L2} = 0.75$$

$$\text{L4} = 0.86$$

$$\text{M1} = 0.55$$

In general, $q_{\text{gra}} < q_{\text{sil}}$

Fixing q_{gra} and varying q_{sil} do not make a difference

Fixing q_{sil} and varying q_{gra} produce great variations in the slope ratio

WHICH DUST POPULATION EXERTS A GREATER INFLUENCE?

Far-UV slope

$$b_{\text{FUV}}/b^{\text{MRN}}$$

$$\text{H1} = 0.76$$

$$\text{H2} = 0.79$$

$$\text{H4} = 0.75$$

$$\text{L1} = 0.78$$

$$\text{L2} = 0.75$$

$$\text{L4} = 0.86$$

$$\text{M1} = 0.55$$

In general, $q_{\text{gra}} < q_{\text{sil}}$

Fixing q_{gra} and varying q_{sil} do not make a difference

Fixing q_{sil} and varying q_{gra} produce great variations in the slope ratio

CONCLUSION

Variations in the FUV slope of the UV extinction curve mainly arise from depletion of small graphite grains that return to gas phase
